

Collections Data Quality Report

Payment integrity

346 duplicate successful payment rows were found. Deduplication by payment_id removes ■2.59 Cr. payment_reference is reused across multiple accounts and is not a safe transaction key.

Identity integrity

The account master and event-level borrower_id values disagree at very high rates. Account-level recovery is therefore anchored on account_id. Borrower-level attribution should retain a mismatch flag rather than silently rewriting source identifiers.

Agent identity

Agent IDs have multiple names, employee codes and joined dates. Agent performance and tenure are not treated as causal or production-grade until a temporal identity master is established.

Time and vendor handling

Multiple timezones occur for vendors. Calling-hour comparisons use raw event hour only and are explicitly labelled descriptive. A production implementation should convert event timestamps using a governed timezone policy.

Campaign definitions

Campaign names can map to multiple strategy versions and target definitions. Campaign_id and strategy_version should be used together for analysis.

Denominator integrity

The primary conversion denominator is one first target per account-month. Channel totals are not assumed to be mutually exclusive across an account lifetime. This prevents repeated targeting events from changing the denominator silently.

August

August contains partial observed days and is excluded from full-month trend claims.

Business impact

The largest quantified integrity issue is payment duplication. Attribution-window choice materially changes attributed recovery, and account-event identity mismatches are a major analytical risk. Both should be monitored as production checks.
